Abstract. Dental caries is a biofilm-dependent oral disease, and fermentable dietary carbohydrates are the key environmental factors involved in its initiation and development. However, among the carbohydrates, sucrose is considered the most cariogenic, because, in addition to being fermented by oral bacteria, it is a substrate for the synthesis of extracellular (EPS) and intracellular (IPS) polysaccharides.

The term ' dental caries ' implies cavities and tooth decay. Tooth decay primarily occurs due to bacteria that include Streptococcus sobrinus and various mutans. These bacteria convert glucose or fructose present in the mouth to acids such as lactic acid. The tooth enamel gets destructed or damaged due to acids produced by bacteria.

Dental caries is a transmittable infectious disease with a central role of bacteria instrumenting the onset of caries formation. Human oral cavity harbours numerous microbes which are not yet been able to culture or investigate. The present study was aimed to characterize the microbial population associated with the dental caries using culture dependent and culture independent approaches. Various biochemical characterization including Biofilm Formation analysis, Antibiotic Assay and 16s rRNA gene amplification were performed to investigate the culture dependent analysis of microbial flora associated with dental caries. Biofilm formation test revealed that the oral bacterial strains formed better biofilms. Also, molecular approach of recombinant DNA technology (Metagenomics) was employed for culture independent analysis of microbial flora associated with dental caries.

Dental caries is an irreversible microbial disease of the calcified tissues of the teeth, characterized by demineralization of the inorganic portion and destruction of the organic matrix of the tooth which often leads to cavitation. Dental caries because of its uniqueness as a disease remains as one of man's most common, oldest and singly costliest ailment. There are practically no geographic areas in the world whose inhabitants do not exhibit some evidence of dental caries. The earliest detectable stage is the appearance of a white spot on the tooth. Caries is slowly progressing microbial disease which, if not intercepted and terminated at the right point in time, may lead to conditions like acute and chronic pulpitis, granuloma, abscess and eventually cyst around the apex of offending tooth leading to cellulitis.
